### **ABSTRACT**

Five types of related graphs which are of recent use in mathematical chemistry are considered. The notion of "equivalent" graphs is introduced which seems to be of value in connection with data reduction.

### INTRODUCTION

The past twenty-five years witnessed serious chemical applications of discrete mathematics (mainly graph theory (ref. 1), combinatorics (ref. 2), number theory (ref. 3), and group theory (ref. 2)) which led to what is known today as "chemical" graph theory (ref. 4). The structure-resonance theory of Herndon (ref. 5), the conjugated circuits model (independently introduced by Randic (ref. 6) and by Gomes (ref. 7)) and the topological theory of resonance (refs. 8, 9) are illustrative examples of such models. An interesting combinatorial concept, the introduction of which in chemistry is mainly due to Hosoya and coworkers (ref. 10) is that of nonadjacent This latter concept can be made to unify many related structures. combinatorial polynomials in chemistry and physics (ref. 4) as shown in Chart:

### NONADJACENT STRUCTURES

EDGES	VERTICES	HEXAGONS	CELLS
p(T;k)	ο(Λ ;k)	r(B;k)	κ(P;k) ρ(P <sub>r</sub> ;k)
Matching	Color, Independence	Sextet	King Rook

Graph Theory

Dato Reduction

The above terms are explained in Table 1 which contains polynomials of chemistry and physics. The general form of the polynomials given in Table 1 is given by

$$(G;x) = \sum_{k=0}^{m} (G;k) x (k,n)$$
 (1)

## **EQUIVALENT GRAPHS**

Fig. 1 shows five types of graphs most commonly considered in mathematical chemistry, viz., a caterpillar tree (ref. 11), T, a polyhex graph (ref. 12) of a benzenoid hydrocarbon, B, a Clar graph (ref. 13),  $\Lambda$ , a king polyomino graph (ref. 14), P and a rook board  $P_r$  (ref. 15).

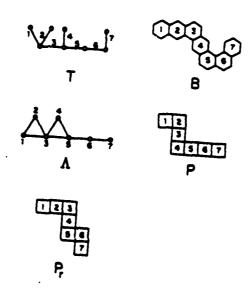

Fig. 1. A set of five equivalent graphs: a caterpillar tree, T, a polyhex graph, B, a clar graph, A, a king polyomino, P, and a rook board,  $P_r$ .

The following identities can easily be verified

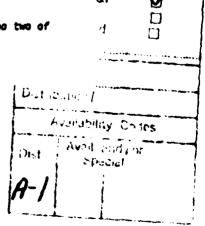

$$H(T;x) = \sigma(B;x) = \omega(\Lambda;x) = K(P;x) = R(P_T;x)$$
  
= 1 + 7x + 13x<sup>2</sup> + 6x<sup>3</sup>.

There is a one-to-one correspondence between any two of the invariants of each graph. For example the edges of T (arbitrarily labeled as shown) can be mapped onto the hexagons of B and so on: k edges in T are incident only if k hexagons in B are nonresonant, k vertices in  $\Lambda$  are adjacent or k cells in P or  $P_T$  are adjacent. In P two cells are adjacent if they share one vertex. Two cells are adjacent in  $P_T$  if they are in the same row. Fig. 2 illustrates the one-to-one correspondence between the adjacency relations of the five types of graphs for k=3. Sets of graphs such as shown in Fig. 1 will be called equivalent graphs 16.

Table 1 Polynomials, associated graphs and graph invariants in chemistry and physics.

Polynamial	٥	Graph-Invariants	Associated Graph	e(6;k)	f(k,n)
1. Acyclic •	(-1) <sup>k</sup>	set of edges	Caterpillar Tree.	p(G;k)ª	n-2k

- H(G;x) 3. Sextet,	1	set of hexagons	T Polyhex Graph,	r(B;k)b	k
* σ(8;x) 4. King	ı	set of cells	B Polyamina Graph,	«(P;k)C	k
# K(P;x) 5. Rook,	1 er	set of cells	Polyomino Graph,	o (Pr;k)d	k or
<ul><li>E K(P<sub>r</sub>;x)</li><li>6. Independence,</li></ul>	(-1) <sup>k</sup>	set of vertices	P Clar graph	Q(A ;k)®	n-2k k
w(A ;x) 7. Color,	1	set of vertices	A Arbitrary graph,	ç(G;k) <sup>f</sup>	k
C(G;x) 8. Resonance,	(-1)k	set of hexagons	6 Polyhex graph,	r(8;k) <sup>5</sup>	24-2k
A(8;x)			8		

- a Number of selections of k independent edges & T( i.e. no two edges are incident)
- b. Number of selections of k nonadjacent but mutually resonant hexagens  $\epsilon$  B
- c Number of ways of arranging k nontaking kings on a polyomino graph.
- d Number of ways of arranging k non-attacking kings
- e Number of selections of k independent vertices  $\epsilon A$  . (No two are adjacent)
- f Number of colorings in 6 in which there are k vertices of the same color so that no two of them are adjacent.

### CONJECTURE

The graph theoretical properties (which depend only on connectivity relations between vertices) of a graph are preserved in any of its equivalent graphs. A similar conjecture applies to the <u>physical properties</u> (i.e. observables) which depend mainly on the graph adjacency matrix.

# TEST OF CONJECTURE AND RESULTS

If our conjecture is true it would be possible (and, in fact, desirable) to study a <u>larger</u> graph, such as a polyhex graph of a benzenoid system in terms of <u>much smaller</u> equivalent caterpillar tree, or its line graph: the corresponding Clar graph. Fig. 3-5 illustrates such studies where one physical and two graph-theoretical (combinatorial) properties are studied. In all cases the molecular connectivity index of Randic (ref. 17),  $\chi$ , is used and is given by

$$h_{\chi} = \int (v_1 v_1 \dots v_{h+1})^{-\frac{1}{2}}$$
 (2)

where the summation is taken over all paths in the graph. Table 2 shows percent retrieval of a property for one representative case. The concept illustrated here seems to be of value in data reduction.

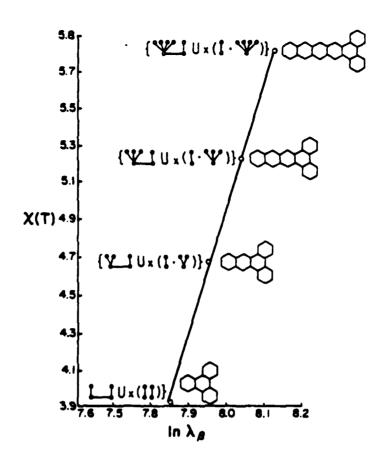

Fig. 3. A plot of electronic absorption B band,  $\lambda B$ , for a series of branched benzenoids  $^{18}$  and the connectivity indices of a series of disconnected trees, (T).

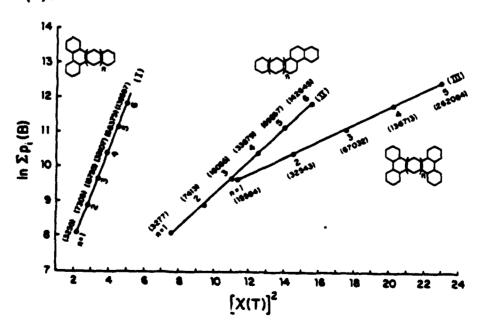

Fig. 4. Correlation between total number of self-avoiding paths,  $^{19}$   $^{\Sigma}$  p(B), (numbers of parentheses) of families of benzenoid hydrocarbons and  $[x(T)]^2$ , the squares of connectivity indices of the equivalent trees.

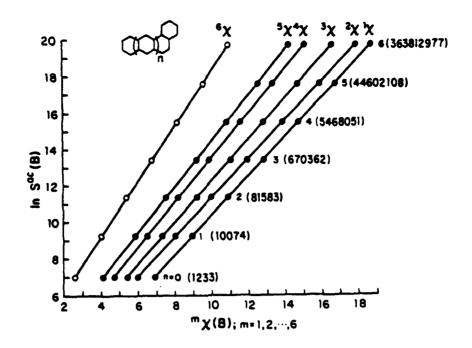

Fig. 5. Correlation between the total number of acyclic Sachs graphs, $^4$ ) Sac(B), (numbers in parentheses) for a series of polyhex graphs with their molecular connectivity indices, (B) up to sixth order.

# Table 2

Percent retrieval of the total number of self-avoiding paths for the series of nonbranched hydrocarbons shown in Fig. 4. The regression line is Y = 4.374 + 0.484 X with a correlation coefficient = 1.0000.
